Electropalatography (EPG)

- ▷ A plastic pseudopalate fitted to a person's mouth detects the presence or absence of contact between the tongue and the palate in 62 different locations during an utterance (sampled at 200 Hz).
- ▷ Result: sequence of 62-dimensional binary EPG frames.
- ▷ Data reduction necessary, traditionally via fixed linear indices.
- ▷ ACCOR-II database: synchronised data (EPG, acoustic, etc.) for different utterances and speakers.
- ▷ The mapping phoneme-to-EPG is not one-to-one, e.g. [æ]/[ə] or [d]/[t].

Electropalatography (cont.)

Pseudopalate and representative EPGs for the typical stable phase of different phonemes.

The Reading pseudopalate.

Latent variable models

- ▷ Marginalisation in latent space: $p(\mathbf{t}) = \int p(\mathbf{t}|\mathbf{x})p(\mathbf{x}) d\mathbf{x}$.
- ▷ Maximum likelihood parameter estimation: $l(\Theta) = \sum_{n=1}^N \log p(\mathbf{t}_n|\Theta)$.
- ▷ Inverse mapping given by informative point (mean, mode) of posterior: $p(\mathbf{x}|\mathbf{t}) = \frac{p(\mathbf{t}|\mathbf{x})p(\mathbf{x})}{p(\mathbf{t})}$.

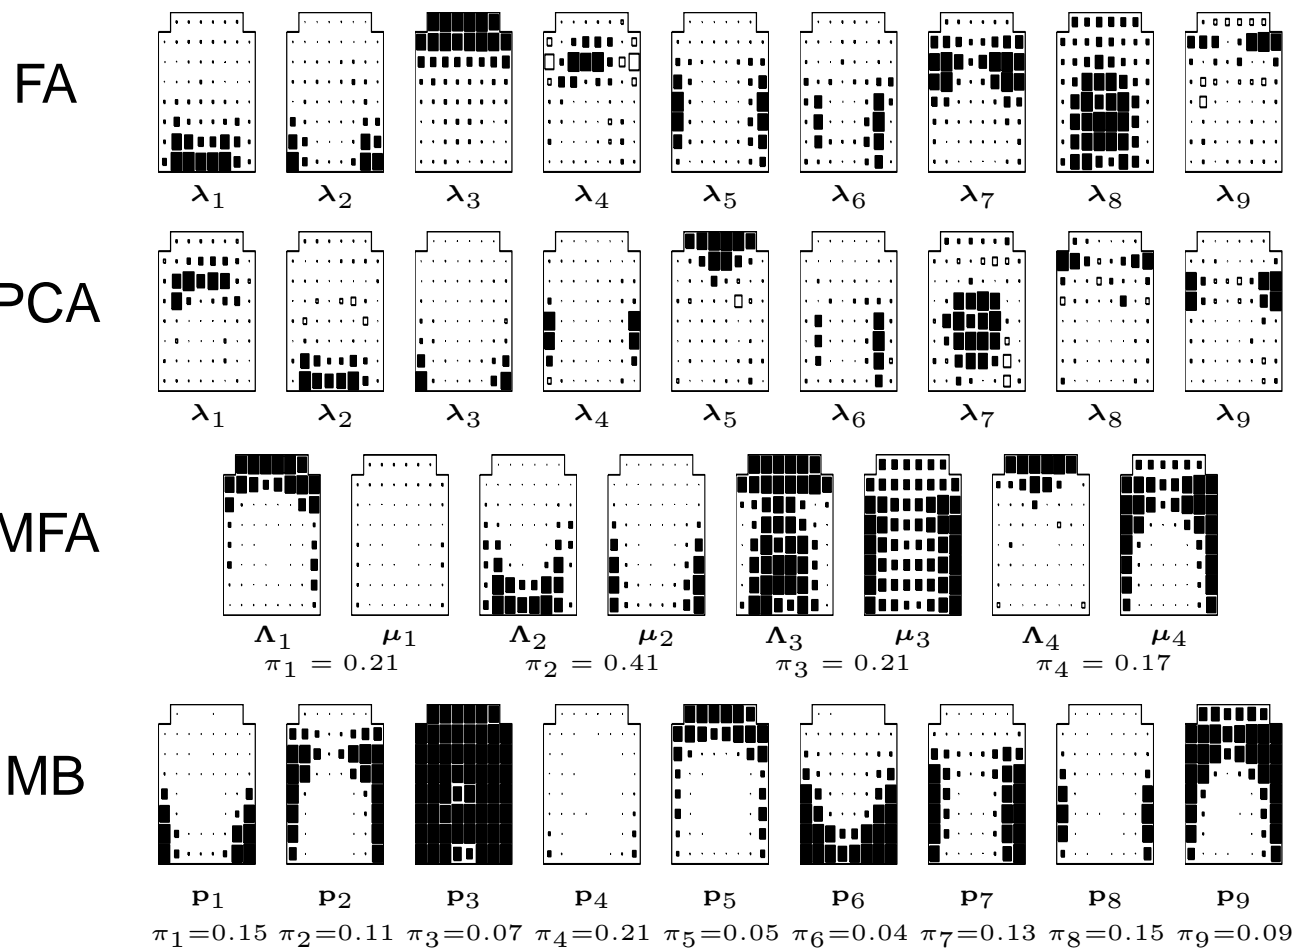

Examples of latent variable models

- ▷ Factor analysis: prior is normal $\mathcal{N}(\mathbf{0}, \mathbf{I})$, mapping is linear, noise model is normal with diagonal covariance matrix.
- ▷ PCA: like FA but noise model has isotropic covariance.
- ▷ GTM: prior is uniform over discrete latent grid, mapping is a generalised linear model, noise model is normal with isotropic covariance matrix.
- ▷ Mixtures of factor analysers (one mean parameter and one factor per analyser, noise model covariance matrix common to all analysers).

We also tried mixtures of multivariate Bernoulli distributions (not really a latent variable model).

All these models can be trained via an EM algorithm.

Factors / prototypes (speaker RK)

Log-likelihood and reconstruction error (speaker RK)

Log-likelihood

Two-dimensional representation (speaker RK)

Factor analysis

GTM

Trajectory in latent space of the highlighted utterance fragment “I prefer **Kant** to Hobbes for a good bedtime book” (/aɪ prɪ'fɜ 'kænt tə 'hɒbz fɜ ə 'gʊd 'bedtaɪm 'bʊk/).

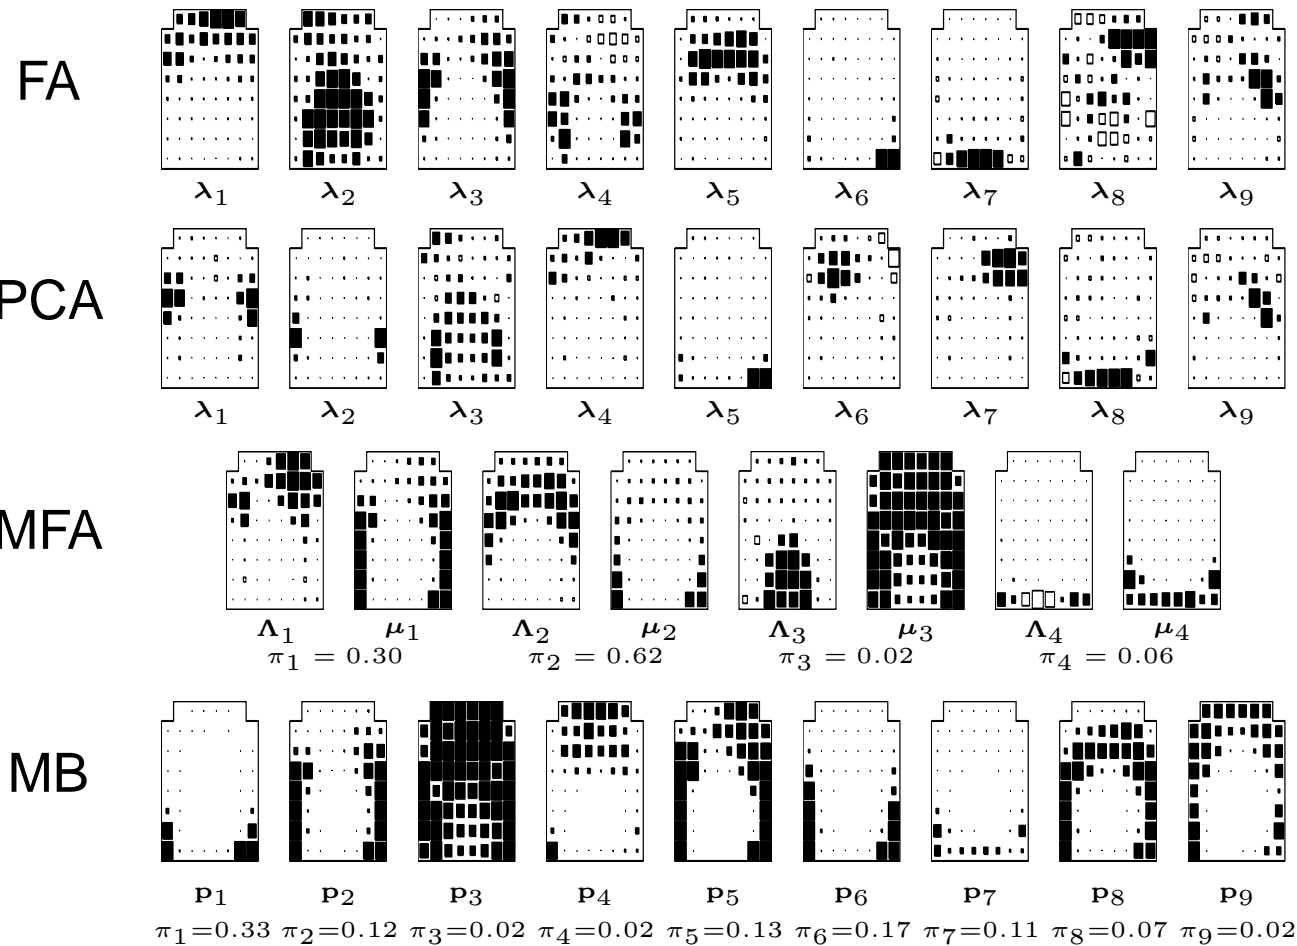

Conclusions

- ▷ Adaptive methods outperform fixed data reduction indices.
- ▷ PCA and FA performed similarly in terms of likelihood.
- ▷ Mixtures of factor analysers and multivariate Bernoulli distributions did not perform well.
- ▷ Two-dimensional GTM outperformed all other methods in terms of likelihood and error reconstruction and reveals nonlinear structure in the data.
- ▷ This suggests a low intrinsic dimensionality for the EPG data.

Factor analysis

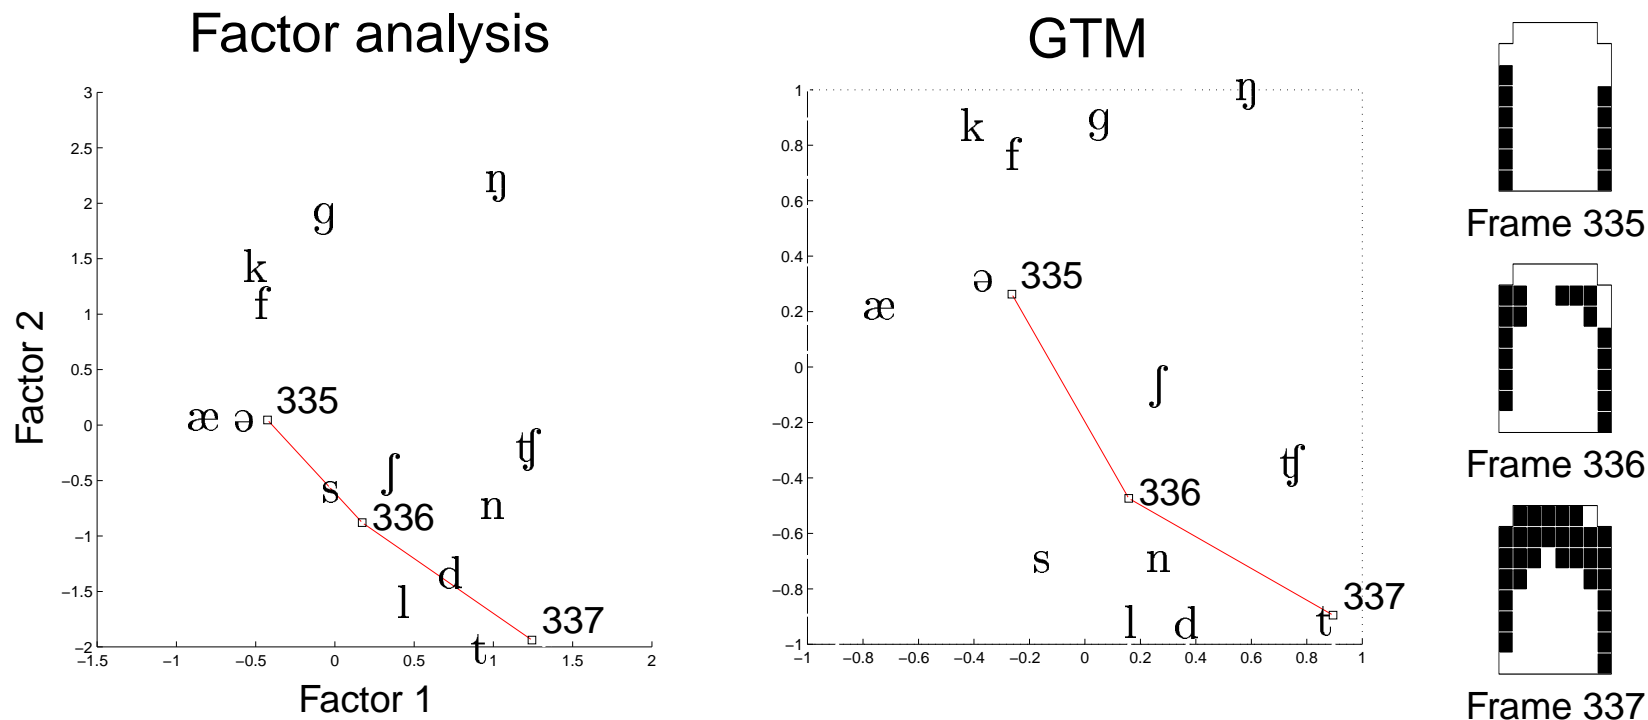

GTM

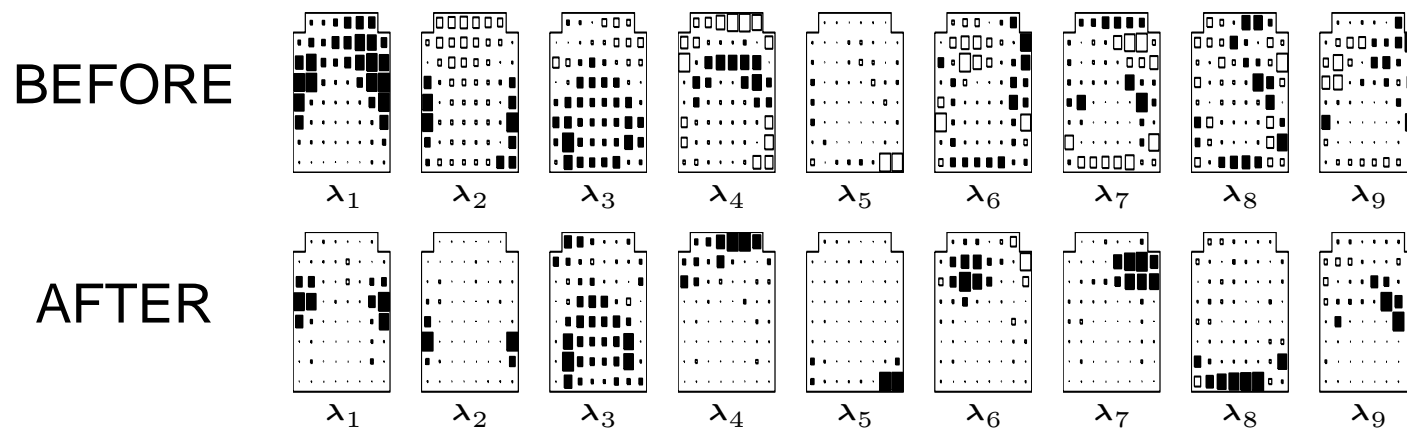

Trajectory in latent space of the highlighted utterance fragment “I prefer **Kant** to Hobbes for a good bedtime book” (/aɪ prɪ'fɜ 'kænt tə 'hɒbz fɜ ə 'gʊd 'bedtaɪm 'bʊk/).

Discontinuities in latent space (speaker RK)

Selected subsequence of the utterance fragment “I prefer **Kant** to Hobbes for a good bedtime book” (/aɪ prɪˈfɜː ˈkænt tə ˈhɒbz fɜː ə ˈɡʊd ˈbedtɑɪm ˈbʊk/). The abrupt transition from /æ/ to /nt/ (frames 335–336) produces a discontinuity in latent space.

PCA factors before and after varimax rotation (speaker HD)

Both sets of components span the same linear subspace, but the varimax-rotated one is more easily interpretable.
