

Total possible marks: 100. Homeworks must be solved individually. This set covers chapters 1–4 of the textbook *Introduction to Algorithms*, 3rd. ed., by Cormen et al.

Exercise 1: asymptotic behavior (20 points).

- (10 points) Assume you have two computers, C_A and C_B , capable of performing 10^6 and 10^8 operations per second, respectively. Both computers run a set of algorithms whose precise complexities $f(n)$ are given below. Determine the size n^* of the biggest input that can be processed in 1 second for each computer, as in the example.

$f(n)$	n^* for C_A	n^* for C_B
$\lg \lg n$	10 ¹²	10 ¹⁶
\sqrt{n}		
$14n + 4$		
$n \log_3 n + n$		
$n^2 + 7n$		
n^{10}		
2^n		
3^n		
$n!$		
n^n		

The precise complexity tells you how many operations are performed to solve an instance of size n . Assume each operation takes the same time and that the input sizes are natural numbers $1, 2, 3, \dots$

- (10 points) Prove formally that $f(n) = an^2 + bn + c$ where $a > 0$ is $\Theta(n^2)$. *Hint:* find values for the constants c_1, c_2, n_0 in the definition of $\Theta(\cdot)$ and show it holds.

Exercise 2: sorting algorithms, correctness and runtime (44 points). Consider an algorithm INSERTION-MERGE-SORT with the following pseudocode:

```

INSERTION-MERGE-SORT( $A, p, r$ )
1  if  $p < r$ 
2       $q = \lfloor (p + r)/2 \rfloor$ 
3      INSERTION-MERGE-SORT( $A, p, q$ )
4      INSERTION-MERGE-SORT( $A, q + 1, r$ )
5      INSERTIONMERGE( $A, p, q, r$ )
    
```

where the INSERTIONMERGE algorithm has the following pseudocode:

```

INSERTIONMERGE( $A, p, q, r$ )
1  for  $j = q + 1$  to  $r$ 
2       $key = A[j]$ 
3       $i = j - 1$ 
4      while  $i \geq p$  and  $A[i] > key$ 
5           $A[i + 1] = A[i]$ 
6           $i = i - 1$ 
7       $A[i + 1] = key$ 
    
```

1. (9 points) Prove that INSERTIONMERGE solves the same problem as the MERGE algorithm on p. 30–31 in the textbook but works in place. *Hint*: use a loop invariant.
2. (3 points) Prove that INSERTION-MERGE-SORT sorts the input array A . *Hint*: use induction.
3. (6 points) Identify the best and worst case of INSERTIONMERGE and compute the runtime $T(n)$ in asymptotic notation for each. Be explicit about summing the number of iterations in the loops.
4. (8 points) Identify the best and worst case of INSERTION-MERGE-SORT and compute the runtime $T(n)$ in asymptotic notation for each. Give the recurrence explicitly for each.
5. (5 points) Imagine that the partition in INSERTION-MERGE-SORT in two subarrays is $(\frac{9}{10}n, \frac{1}{10}n)$ instead of $(\frac{1}{2}n, \frac{1}{2}n)$. Give the recurrence and its runtime again (consider only the best case).
6. (4 points) Is INSERTION-MERGE better than MERGE? Is INSERTION-MERGE-SORT better than INSERTION-SORT or MERGE-SORT? Consider the complexity in time and memory for each case.
7. (9 points) Give the pseudocode for an algorithm SELECTION-MERGE-SORT(A, p, r) that modifies SELECTION-SORT(A) (exercise 2.2-2) in the same way as INSERTION-MERGE-SORT modified INSERTION-SORT, so that it can merge two sorted arrays. Identify its best and worst case and compute the runtime $T(n)$ in asymptotic notation for each. Based on this, would this improve over INSERTION-MERGE-SORT? Explain.

Exercise 3: recurrent equations (36 points). (This is based on textbook problems 4.1 and 4.3.) Give asymptotic upper and lower bounds for $T(n)$ in each of the following recurrences. Assume that $T(n)$ is constant for $n \leq 2$.

1. (6 points) $T(n) = T(9n/10) + n\sqrt{n}$
2. (6 points) $T(n) = T(\sqrt{n}) + 1$
3. (6 points) $T(n) = 2T(2n) + n^2$
4. (6 points) $T(n) = 7T(n/2) + n^2 + 3n + 1$
5. (6 points) $T(n) = T(n - 1) + n$
6. (6 points) $T(n) = 2T(n/4) + \sqrt{n}$

Justify your answers. If you use the master theorem, specify which case and show that its hypotheses are satisfied. If you use recursion trees to find a good guess, verify the guess with the substitution method.

Bonus exercise: recurrent equations (10 points). Consider the recurrence

$$T(n) = aT(n/b) + f(n).$$

Case 3 of the master theorem requires that $f(n) = \Omega(n^{\log_b a + \epsilon})$ for some constant $\epsilon > 0$ and that $f(n)$ satisfies the regularity condition $af(n/b) \leq cf(n)$ for some constant $c < 1$ and all sufficiently large n . Prove that the regularity condition is always satisfied if $f(n) = n^k$. (This means we don't need to check it when f is a polynomial.)

Bonus exercise: recurrent equations (30 points). Consider the following particular type of recurrence:

$$T(n) = \begin{cases} 1, & n = 1 \\ aT(n/b) + n^c, & n > 1 \end{cases}$$

where $a \geq 1$ and $b > 1$ are integers, and $k = \log_b n$ is integer (that is, we can only pick sizes n of the form $n = b^k$ where $k \geq 0$ is an integer). Use mathematical induction to prove that

$$T(n) = \begin{cases} n^c(1 + \log_b n), & \text{if } c = \log_b a \\ \frac{a}{b^c} n^{\log_b a - n^c}, & \text{if } c \neq \log_b a. \end{cases}$$

Hint: as a simpler example, see exercise 2.3-3.

Consequently, prove the master theorem for this recurrence, that is, prove that

$$T(n) = \begin{cases} \Theta(n^{\log_b a}), & \text{if } c < \log_b a \\ \Theta(n^c \lg n), & \text{if } c = \log_b a \\ \Theta(n^c), & \text{if } c > \log_b a. \end{cases}$$
